

MotIQ Website Brief and Copy Guide

Purpose of this document

This document is written for a web designer, developer, or marketing writer who needs clear direction to build the MotIQ website. The website should focus on client benefits, business impact, and the practical problems MotIQ helps solve.

The tone should be professional, credible, industrial, and easy to understand. Avoid overly academic language. Lead with value, savings, uptime, reliability, and visibility.

1. What MotIQ is

MotIQ is an intelligent motor monitoring platform that helps operators, facility managers, and maintenance teams detect developing motor and power issues early, reduce unplanned downtime, improve maintenance decisions, and lower energy waste.

It combines electrical, operational, thermal, and condition insight into one system.

MotIQ does not only show raw numbers. It turns those numbers into useful warnings, condition awareness, and decision support.

2. Main website focus

The website should answer these questions clearly:

- What problems does MotIQ solve?
- Why should a client care?
- How does MotIQ save money?
- How does it reduce downtime and risk?
- What parameters does it monitor?
- How do those parameters relate to motor health, energy consumption, and maintenance costs?
- Why is early detection valuable to the client's bottom line?

The website should focus more on outcomes than on hardware details.

3. The business problems MotIQ helps solve

Many clients do not have enough visibility into what is happening inside their motors and electrical systems until performance drops or a failure occurs.

Common problems include:

- Unexpected motor failures
- High energy consumption without a clear reason
- Repeated nuisance trips or unexplained stoppages
- Frequent starts and stops that shorten equipment life
- Low power factor and avoidable electrical inefficiency
- Mechanical issues that develop slowly and go unnoticed
- Electrical imbalance that increases heating and stress
- Maintenance that is reactive instead of planned
- Hidden bearing or rotor problems that become expensive failures
- Overheated contactors and related control panel issues
- Poor power quality that affects reliability and performance

MotIQ is intended to make these hidden problems visible earlier.

4. Core website message

Main positioning statement

MotIQ helps clients predict, prevent, and protect.

Expanded message

MotIQ continuously monitors the electrical, mechanical, and operational behavior of motor-driven assets so teams can identify developing problems earlier, reduce energy waste, improve uptime, and make better maintenance decisions.

5. Key client benefits

These should appear throughout the website.

Reduce unplanned downtime

By identifying developing issues earlier, MotIQ helps teams intervene before a motor or driven system fails unexpectedly.

Reduce energy waste

By monitoring low power factor, unbalance, poor power quality, abnormal loading, and repeated starts and stops, MotIQ helps clients uncover avoidable electrical losses and inefficient operating conditions.

Protect equipment life

MotIQ helps detect conditions that increase heating, vibration, stress, and wear, allowing clients to act before these conditions shorten motor life.

Improve maintenance planning

Instead of reacting after failure, teams can schedule inspection or service when warning signs first appear.

Improve visibility and confidence

Clients gain a clearer understanding of motor condition, operating behavior, and electrical performance.

Support better financial decisions

MotIQ helps convert technical data into business decisions by showing where energy, uptime, and maintenance costs can be improved.

6. Parameters MotIQ checks

These should appear on the website in a clear, client-friendly way.

Electrical and power parameters

- Low power factor
- Active power
- Reactive power
- Power quality
- Unbalance
- Frequent start and stop activity

Condition and fault-related indicators

- Eccentricity
- Misalignment
- Broken rotor bar indication
- Bearing issue indication
- Predictive alarm indicators
- Active alarm indicators

Related operational and thermal visibility

- Motor contactor temperature
 - Start activity trend
 - Condition confidence / advisory level
-

7. Why these parameters matter to clients

This section is important for the website because it connects technical monitoring to business value.

Low power factor

Low power factor means the system is drawing more current than necessary for the useful work being done. This can increase losses, increase heating, reduce electrical efficiency, and in some facilities may contribute to utility penalties or reduced system capacity.

Client value: better efficiency, lower losses, improved system performance, reduced avoidable energy cost.

Frequent start / stop activity

Frequent starts increase thermal and mechanical stress on motors, starters, and connected equipment. This can shorten equipment life and increase energy use during repeated restart cycles.

Client value: reduced wear, better reliability, fewer avoidable stoppages, improved motor life.

Unbalance

Voltage or current unbalance can increase motor heating and reduce efficiency. Even a moderate imbalance can create extra stress on the motor windings and affect reliability.

Client value: less heating, lower stress, better reliability, reduced chance of early motor damage.

Eccentricity

Eccentricity can indicate uneven air gap or rotor-related issues. Left untreated, it may lead to performance loss, heating, or further mechanical and electrical damage.

Client value: earlier correction, lower risk of escalation, reduced repair cost.

Misalignment

Misalignment causes extra mechanical stress, vibration, and energy waste. It can reduce the life of bearings, couplings, and the motor itself.

Client value: lower energy waste, reduced wear, improved reliability.

Broken rotor bar indication

Rotor issues can reduce motor efficiency, increase losses, and develop into more serious problems if ignored.

Client value: early warning before serious performance loss or major motor repair.

Bearing issue indication

Bearing problems are one of the most common causes of motor failure. Early warning can allow replacement during planned downtime instead of emergency shutdown.

Client value: lower repair cost, reduced collateral damage, less unplanned downtime.

Active and reactive power

Tracking active and reactive power helps clients understand how the motor is actually performing and whether it is operating efficiently.

Client value: clearer visibility into real consumption and inefficient conditions.

Motor contactor temperature

Overheated contactors can indicate poor connections, overload conditions, contact wear, or developing electrical risk inside the panel.

Client value: better electrical safety, reduced contactor failure risk, improved control reliability.

Power quality

Poor power quality can affect motor performance, increase stress, and lead to lower efficiency or nuisance issues.

Client value: improved system reliability, better performance, earlier visibility into electrical environment problems.

8. How MotIQ helps save energy

This should be a dedicated section on the website.

Main message

MotIQ helps save energy by identifying operating conditions that waste power, increase losses, or force equipment to work harder than necessary.

Website explanation

Energy waste is not always caused by one dramatic failure. Often it comes from smaller issues that remain hidden over time, such as:

- low power factor
- repeated starts and stops
- electrical unbalance
- misalignment
- mechanical drag from developing faults
- poor power quality
- overload-related heating

By making these conditions visible early, MotIQ helps clients correct them before they become routine energy losses.

Website phrasing suggestion

MotIQ helps clients move from simply consuming power to understanding how power is being used, where it is being wasted, and what actions can improve efficiency.

9. How MotIQ reduces downtime and risk

Main message

MotIQ reduces risk by detecting developing conditions earlier, so teams can act before a fault becomes an outage.

Website explanation

When issues such as bearing degradation, rotor problems, unbalance, or frequent starts are caught early, maintenance can be planned in a controlled way. That means:

- fewer surprise shutdowns
- fewer emergency callouts
- less production disruption

- lower repair cost
- lower risk of secondary damage

Website phrasing suggestion

The value of MotIQ is not only in detecting faults. It is in creating time to respond before failure affects operations.

10. Example ROI and business-impact cases for the website

These are example scenarios to help communicate financial value. They should be presented as illustrative examples, not guaranteed results.

Case example 1: energy savings from low power factor and unbalance

A facility operates a 30 kW motor-driven system 6,000 hours per year.

If electrical inefficiency and poor operating conditions increase effective energy use by only 5%, that equals:

- $30 \text{ kW} \times 6,000 \text{ h} = 180,000 \text{ kWh}$ per year
- 5% avoidable loss = 9,000 kWh per year
- at \$0.12 per kWh = \$1,080 per year on one asset

If the same issue exists across 10 similar assets: - $\$1,080 \times 10 = \$10,800$ per year

Website takeaway: small inefficiencies repeated over many hours and many motors become meaningful costs.

Case example 2: downtime avoidance from early bearing warning

A critical motor failure causes 8 hours of downtime.

Assume the cost of lost production, labor disruption, contractor response, and repair is: - $\$2,500$ per hour of downtime - 8 hours = $\$20,000$

If early warning allows the bearing to be replaced during planned maintenance for: - $\$1,500$ planned repair cost

then the avoided business impact can be approximately: - $\$20,000$ avoided downtime cost minus $\$1,500$ planned repair = $\$18,500$ of avoided disruption impact

Website takeaway: early warning can turn a major interruption into a manageable maintenance task.

Case example 3: frequent starts and equipment wear

A motor with excessive start/stop cycles experiences more thermal stress and faster wear on contactors and related equipment.

If repeated stress leads to: - one avoided emergency service visit of \$1,200 - one avoided starter replacement of \$1,800 - reduced operating disruption worth \$3,000

total impact may exceed: - \$6,000 on a single recurring problem

Website takeaway: operational behavior matters, not just fault alarms.

Case example 4: contactor overheating risk

A hot contactor inside a panel may be an early sign of connection issues or abnormal current stress.

If detected early, the issue may require: - tightening, inspection, or planned replacement costing a few hundred dollars

If missed, it could lead to: - starter failure - motor outage - emergency electrician visit - production interruption

A small temperature warning can therefore prevent a much larger cost event.

Website takeaway: small electrical warnings often carry large risk value.

11. Suggested homepage copy

Hero headline options

- Predict. Prevent. Protect.
- Smarter Motor Monitoring for Reliable Operations
- Reduce Downtime. Improve Efficiency. Protect Critical Motors.

Hero subheading

MotIQ helps clients detect developing electrical and mechanical issues early, reduce energy waste, improve uptime, and make better maintenance decisions across motor-driven assets.

CTA buttons

- Request a Demo
 - Talk to Sales
 - See How MotIQ Works
-

12. Suggested website page structure

Home

High-level benefits, key value, and strong call to action.

Why MotIQ

Problems clients face and why traditional reactive maintenance is costly.

What MotIQ Monitors

Clear explanation of the monitored parameters and why they matter.

Benefits and ROI

Energy savings, downtime reduction, asset protection, and bottom-line impact.

Applications

Pumps, fans, compressors, conveyors, HVAC systems, and other motor-driven assets.

Condition Insight

Explain active alarms, predictive alarms, confidence levels, and trend-based insight.

Contact / Demo

Simple page for inquiry, contact, and sales discussion.

13. Suggested section for “What MotIQ Monitors”

Headline

MotIQ Monitors the Conditions That Matter Most

Intro line

MotIQ tracks the electrical, mechanical, and operational indicators that most often drive energy loss, equipment stress, and unplanned downtime.

Monitored conditions list

- low power factor
- active and reactive power
- power quality

- start/stop frequency
 - unbalance
 - eccentricity
 - misalignment
 - broken rotor bar indication
 - bearing issue indication
 - motor contactor temperature
 - active alarms
 - predictive alarms
-

14. Suggested section for “Business Impact”

Headline

Why Early Detection Matters to the Bottom Line

Short text

When inefficient or abnormal conditions remain hidden, the cost is rarely limited to energy alone. The real impact often appears in maintenance cost, production loss, emergency response, reduced equipment life, and avoidable operational risk.

Short bullets

- reduce avoidable energy waste
 - reduce the chance of unexpected shutdowns
 - improve maintenance timing
 - lower risk of secondary equipment damage
 - improve asset reliability and service life
-

15. Suggested section for “Predictive and Active Alarms”

Headline

From Raw Signals to Actionable Insight

Copy

MotIQ distinguishes between early developing conditions and stronger fault evidence.

Predictive alarms highlight emerging patterns that deserve attention before they become failures.

Active alarms indicate stronger fault evidence and support faster decision-making when action is required.

This helps teams avoid both missed warnings and unnecessary overreaction.

16. Visual recommendations for the website team

Use visuals that support business value, not only device beauty.

Recommended visuals: - hero image with MotIQ in industrial setting - Motor Overview screen - Electrical Metrics screen - Thermal Diagnostics screen - Motor Control screen - Condition Status / Predictive Insights screen - benefits graphic showing reduced downtime, improved efficiency, better maintenance planning - ROI or impact card examples using simple numbers

Visual style: - industrial and credible - clean dark blue / charcoal with blue and orange accents - avoid clutter - prioritize readability and trust

17. Short copy blocks for designers to place on the site

Block 1

Detect developing issues before they become costly failures.

Block 2

Reduce energy waste by identifying inefficient operating conditions.

Block 3

Turn motor data into clearer maintenance and operational decisions.

Block 4

Protect uptime, improve reliability, and lower avoidable risk.

18. Final message the website should leave with the visitor

MotIQ is valuable because it helps clients move from reactive response to informed action.

It helps them: - see more clearly - act earlier - waste less energy - reduce costly downtime - protect critical assets - improve the bottom line

19. Final instruction for the website creator

When building the site, always connect each technical parameter to one of these outcomes:

- energy savings
- reduced downtime
- reduced maintenance cost
- reduced operational risk
- longer equipment life
- better decision-making

Do not present monitoring features as isolated technical details. Present them as business tools that improve reliability, efficiency, and financial performance.
